VISUAL BASIC PROGRAMMING 1

Functions & Sub Procedures

In this Lecture:

1. Functions and Sub Procedures.
2. The difference between arguments and parameters.
3. Passing a value by Reference or By Value.
4. Using a RichTextBox control to output information to the user via its *.Text* property and *AppendText* method, setting and using tabs (vbTab), moving to a new line (vbCrLf), changing font colour etc.

Structured Programming:

Structured program design requires that problems be broken into smaller problems to be solved one at a time. Visual Basic has two devices, **Sub procedures** and **Function procedures** that are used to break problems into manageable chunks. To distinguish them from event procedures, Sub and Function procedures are referred to as **general procedures** or **methods**. General procedures also:

1. eliminate repetitive code,
2. can be reused in other programs, and
3. allow a team of programmers to work on a single program.

A **Sub procedure** is a part of a program that performs one or more related tasks, has its own name and is written as a separate part of the program. The simplest type of Sub procedure has the form:

```
Private Sub ProcedureName( param1 As Single, param 2 As Integer etc.)  
    statement(s) that use param1, param2 etc.  
End Sub
```

A Sub procedure is invoked with a statement of the form:

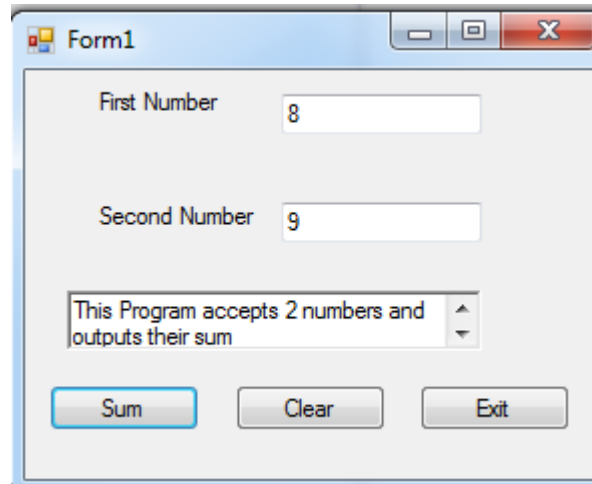

```
Call ProcedureName(argument1, argument2)
```

The word Call is optional. The rules for naming general procedures are identical to the rules for naming variables. The name chosen for a Sub procedure should describe the task it performs.

Sub procedures make a program easy to read, modify, and debug. The event procedure gives a description of what the program does and the Sub procedures fill in the details. Another benefit of Sub procedures is that they can be called several times during the execution of the program. This feature is especially useful when there are many statements in the Sub procedure.

Program 1: Adding Two Numbers using Sub Procedures

This program is a very simple program to add two numbers and to demonstrate the use of Sub procedures. A later exercise (Amortization) will show how they are used for more substantial programming efforts.

```
Public Class Form1
    Private Sub Form1_Load(sender As Object, e As EventArgs) Handles MyBase.Load
        ExplainPurpose()
    End Sub

    Private Sub cmdSum_Click(sender As Object, e As EventArgs) Handles cmdAdd.Click
        Dim sngFirst As Single
        Dim sngSecond As Single
        sngFirst = Val(txtFirstNum.Text)
        sngSecond = Val(txtSecondNum.Text)
        Add(sngFirst, sngSecond)
    End Sub

    Private Sub Add(sng1 As Single, sng2 As Single)
        rtbOutput.Text = "The Sum is: " & (sng1 + sng2)
    End Sub

    Private Sub ExplainPurpose()
        rtbOutput.Text = "This Program accepts 2 numbers and outputs their sum "
    End Sub

    Private Sub cmdClear_Click(sender As Object, e As EventArgs) Handles cmdClear.Click
        txtFirstNum.Text = ""
        txtSecondNum.Text = ""
        rtbOutput.Text = ""
        txtFirstNum.Focus()
    End Sub
End Class
```

The program uses two Sub procedures which are shown highlighted.

The statement `Add(sngFirst, sngSecond)` at 1. causes execution to jump to the `Private Sub Add(sng1 As Single, sng2 As Single)` statement at 2., which assigns the `sngFirst` to `sng1` and the `sngSecond` to `sng2`. After the lines between a Sub procedure statements are executed, execution returns to the line following this call, namely, the `End Sub` statement in the event procedure.

Arguments and Parameters:

The items appearing in the parentheses of a Call statement are called **arguments**. These should not be confused with parameters, which appear in the heading of a Sub procedure. The variables *num1* and *num2* appearing in the Sub procedure *Add* shown below are called **parameters**. They are merely temporary place holders for the numbers passed to the Sub procedure; their names are not important. The only essentials are their **datatype**, **quantity**, and **order**. In the *Add* Sub procedure shown here, the parameters must be numeric variables and there must be two of them.

Figure shows passing arguments to Parameters of a sub procedure. Arguments can be constants, variables or expressions.

Other datatypes can be passed to a Sub procedure e.g. a String. In this case, the receiving parameter in the Sub procedure must be followed by the declaration **As String**.

Passing Arguments ByVal or ByRef:

When you pass a value to a procedure you may pass it **ByVal** or **ByRef** (for by value or by reference). The *ByVal* sends a copy of the argument's value to the procedure so that the procedure cannot alter the original value. The *ByRef* sends a reference to the procedure indicating where the argument's value is stored in memory so that the called procedure can alter the argument's original value. You specify how to pass the argument by using the **ByVal** or **ByRef** keyword before the parameter in the procedure header. If you don't specify **ByVal** or **ByRef** then arguments are **passed by value by default**.

```
Private Sub SelectColor(ByVal IncomingColor As Color)
```

Function Procedures:

Visual Basic has a number of built-in functions that greatly extend its capability. These functions perform such varied tasks as taking the square root of a number **Sqr**, counting the number of characters in a string **Len**, and formatting data **FormatCurrency**. Functions associate with one or more values, called the *input*, and a single value, called the *output*. The function is said to **return** the output value. Often this value is assigned to a variable such as:

```
intCharacters = Len(strSentence)
```

which you can then use in subsequent lines of code. Remember the return value from the `MsgBox` function? This variable must be of the same datatype as the return value.

You can also write your own functions that can be called, calculates a value and returns this value to the caller. Thus the main difference in coding a sub procedure and a function procedure is that in the latter you must set up a **return value**. This return value is placed in a variable that VB names with the same name as the function name.

```
Private Function Commission(ByVal decSalesin As Decimal) As Decimal
..... Commission = decSalesin * 0.35
End Function
```

Note: Somewhere in the function you must set the function name to a value.

Program 2: Calculating Commission using a Function

Looking at the Salary program we covered previously, the commission block could be written as a function and called from within the `cmdCalc_Click` event:

Salary	
Sales	€1,000.00
Commission	€100.00
Tax	
Gross Pay	€1,500.00
Gross Tax	€300.00
Net Tax	€40.00
PRSI	
Weeks Worked	4.34
PRSI	€67.95
Net Pay	€1,492.05

```
Private Sub cmdCalc_Click(sender As Object etc.  
    ' call commission function  
    decCommission = Commission(decSales)  
End Sub
```

```
Private Function Commission(decSalesin As Decimal) As Decimal  
    If decSalesin <= 1000 Then  
        Commission = decSalesin * 0.1  
    ElseIf decSalesin <= 1500 Then  
        Commission = decSalesin * 0.15  
    ElseIf decSalesin <= 2000 Then  
        Commission = decSalesin * 0.2  
    ElseIf decSalesin <= 2500 Then  
        Commission = decSalesin * 0.25  
    ElseIf decSalesin <= 3000 Then  
        Commission = decSalesin * 0.3  
    Else  
        Commission = decSalesin * 0.35  
    End If  
End Function
```

You can also specify the datatype of the return value by adding the **As** clause after the function name.

Here the function can be called within an expression, in which case it doesn't need the **Call** keyword.

When the function is called the value in *decSales* is passed to the function and assigned to the named argument, *decSalesin*. Within the function process for every reference to *decSalesin* the value of *decSales* is actually used.

Program 3: Loan Analysis to demo Functions, Sub Procedures & Output to RichTextBox

Develop a program to analyze a loan. Assume the loan is repaid in equal monthly payments and interest is compounded monthly. The program should request the amount (principal) of the loan, the annual rate of interest, and the number of years over which the loan is to be repaid. The four options to be provided by command buttons are as follows:

1. Calculate the Monthly Payment. The formula for the monthly payment is:

$$\text{Monthly Payment} = P * r / (1 - (1 + r)^{-n}) \text{ or}$$

$$\text{Mon. Payment} = P * \frac{r}{1 - (1 + r)^{-n}}$$

where

P is the principal of the loan,

r is the monthly interest rate (annual rate divided by 12) given as a number between 0 (for 0 percent) and 1 (for 100 percent), and

n is the number of months over which the loan is to be repaid.

Since a payment computed in this manner can be expected to include fractions of a cent, the value should be rounded up to the next nearest cent. This corrected payment can be achieved using the formula:

$$\text{Correct Monthly Payment} = \text{Round}(\text{Monthly Payment} + 0.005, 2)$$

2. Display an Amortization Schedule, that is, a table showing the balance on the loan at the end of each month for any year over the duration of the loan. Also show how much of each monthly payment goes toward interest and how much is used to repay the principal. Finally, display the total interest paid over the duration of the loan. The balances for successive months are calculated with the formula:

$$\text{NewBalance} = (1 + r) * \text{Oldbal} - \text{monPay}$$

where

r is the monthly interest rate (annual rate / 12, a fraction between 0 and 1),

Oldbal is the balance for the preceding month (amount of loan left to be paid), and

monPay is the monthly payment.

3. Show the effect of Changes in the Interest Rate. Display a table giving the monthly payment for each interest rate from 1 percent below to 1 percent above the specified annual rate in steps of one-eighth of a percent.

4. Quit.

Designing the Loan Analysis Program (Hierarchy Chart):

For each of the tasks described in the preceding options 1 to 4, the program must first look at the text boxes to obtain the particulars of the loan to be analyzed. Thus, the first division of the problem is into the following tasks:

1. Input the principal, interest, and duration.
2. Calculate the Monthly Payment.
3. Calculate the Amortization Schedule.
4. Display the effects of Interest Rate Changes.
5. Quit.

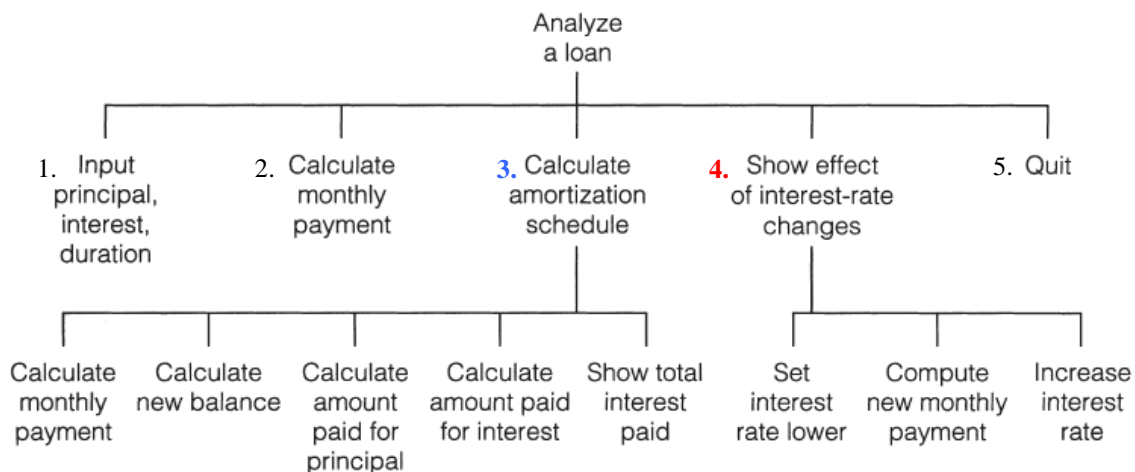

Task 1 is a basic input operation and Task 2 involves applying the formula given in Step 1; therefore, these tasks need not be broken down any further. The demanding work of the program is done in Tasks 3 and 4, which can be divided into smaller subtasks.

3. Calculate Amortization Schedule. This task involves simulating the loan month by month. First, the monthly payment must be computed. Then, for each month, the new balance must be computed together with a decomposition of the monthly payment into the amount paid for interest and the amount going toward repaying the principal. That is, Task 3 is divided into the following subtasks:

- 3.1 Calculate monthly payment.
- 3.2 Calculate new balance.
- 3.3 Calculate amount of monthly payment for principal.
- 3.4 Calculate amount of monthly payment for interest.

4. Display the effects of interest-rate changes. A table is needed to show the effects of changes in the interest rate on the size of the monthly payment. First, the interest rate is reduced by one percentage point and the new monthly payment is computed. Then the interest rate is increased by regular increments until it reaches one percentage point above the original rate, with new monthly payment amounts computed for each intermediate interest rate. The subtasks for this task are then:

- 4.1 Reduce the interest rate by 1 percent.
- 4.2 Calculate the monthly payment.
- 4.3 Increase the interest rate by 1/8 percent.

Hierarchy Chart for Loan Analysis Program

Pseudocode for the Loan Analysis Program:

Calculate Monthly Payment command button:

INPUT LOAN DATA (Sub procedure **InputData**)
COMPUTE MONTHLY PAYMENT (Function **MonthlyPayment**)
DISPLAY MONTHLY PAYMENT (Sub procedure **ShowMonthlyPayment**)

Display Interest Rate Change Table command button:

INPUT LOAN DATA (Sub procedure **InputData**)
DISPLAY INTEREST RATE CHANGE TABLE
(Sub procedure **ShowInterestChanges**)
Decrease annual rate by .01 i.e. 1%
Do
 Display monthly interest rate
 COMPUTE MONTHLY PAYMENT (Function **MonthlyPayment**)
 Increase annual rate by .00125 i.e. going up in steps of 0.125%
Loop Until annual rate > original annual rate + .01 i.e. +1% greater than original

Display Amortization Schedule command button:

INPUT LOAN DATA (Sub procedure **InputData**)
DISPLAY AMORTIZATION SCHEDULE (Sub procedure **ShowAmortSched**)
Compute monthly interest rate
COMPUTE MONTHLY PAYMENT (Function **MonthlyPayment**)
Display amortization table
Display total interest paid

Tasks and Their Procedures:

Task	Procedure
1. Input principal, interest, duration.	InputData
2. Calculate monthly payment.	ShowPayment
3. Calculate amortization schedule.	ShowAmortSched
3.1 Calculate monthly payment.	MonthlyPayment
3.2 Calculate new balance.	Balance
3.3 Calculate amount paid for loan.	ShowAmortSched
3.4 Calculate amount paid for interest.	ShowAmortSched
4. Show effect of interest rate changes.	ShowInterestChanges
4.1 Reduce interest rate.	ShowInterestChanges
4.2 Compute new monthly payment.	MonthlyPayment
4.3 Increase interest rate.	ShowInterestChanges

1. Tasks 3.1 and 3.2 are performed by functions. Using functions to compute these quantities simplifies the computations in [ShowAmortSched](#).

2. Since the monthly payment calculation was rounded up to the nearest cent, it is highly likely that the payment needed in the final month to pay off the loan will be less than the normal monthly payment. For this reason, [Balance](#) (called from [ShowAmortSched](#)) checks if the outstanding balance of the loan (including interest due) is less than the regular monthly payment. If so, it makes appropriate adjustments.

3. The standard formula for computing the monthly payment cannot be used if either:

(i). the interest rate is zero percent or

(ii). the loan duration is zero months.

Although both of these situations do not represent reasonable loan parameters, provisions are made in the function [MonthlyPayment](#) so that the program can handle these situations.

Program 3 - Loan Analysis - The Interface and Functionality

The screenshots show the form design as well as the output in the *rtbDisplay* RichTextBox obtained by clicking the respective command buttons for the given data input.

The screenshot shows the 'Loan Analysis' application window. On the left, there are three input fields: 'Amount of Loan:' with the value '150000', 'Interest APR:' with the value '7', and 'Number of Loan Years:' with the value '30'. Below these fields are four buttons: 'Calculate Monthly Payment' (highlighted with an orange oval), 'Display Interest Rate Change Table', 'Display Amortization Schedule', and 'Quit'. On the right, a RichTextBox displays the text: 'The monthly payment for a €150,000.00 loan at 7.00% annual rate of interest for 30 years is €997.96'.

Monthly Payment for a 30 Year Loan

The screenshot shows the 'Loan Analysis' application window with the same input fields as the previous screenshot. The 'Display Interest Rate Change Table' button is highlighted with an orange oval. The RichTextBox on the right displays a table with the following data:

Annual Interest rate	Monthly Payment
6.000%	€899.33
6.125%	€911.42
6.250%	€923.58
6.375%	€935.81
6.500%	€948.11
6.625%	€960.47
6.750%	€972.90
6.875%	€985.40
7.000%	€997.96
7.125%	€1,010.58
7.250%	€1,023.27
7.375%	€1,036.02
7.500%	€1,048.83
7.625%	€1,061.70
7.750%	€1,074.62
7.875%	€1,087.61
8.000%	€1,100.65

checks if the outstanding balance of the loan (including interest due) is less than the regular monthly payment. e.g. since the monthly payment calculation is rounded up to the nearest cent, it is highly likely that the payment needed in the final month to pay off the loan will be less than the normal monthly payment.
